Question 1 – Create an Application Load Balancer (10 Marks)
Create an Application Load Balancer that distributes traffic between two EC2 instances. Verify that requests are served by both instances.

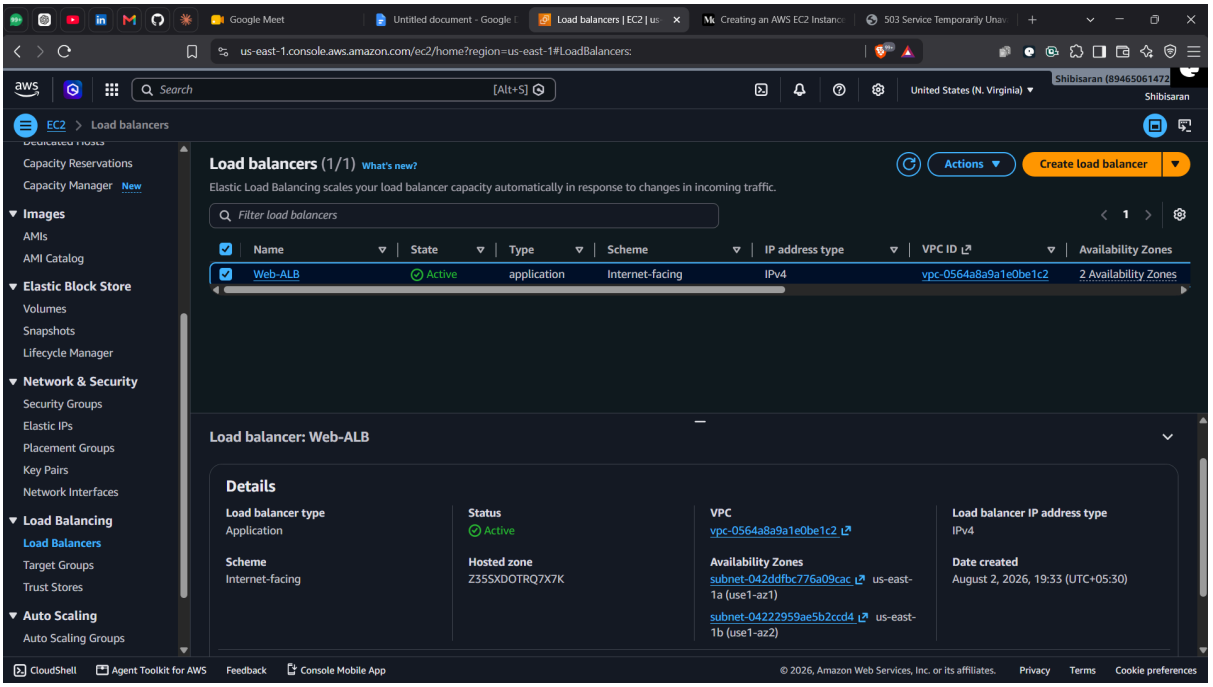

Step 1 Launching two web servers with ssh and HTTP inbound network security groups

Step 2 create target group

Step 3 create application load balancer

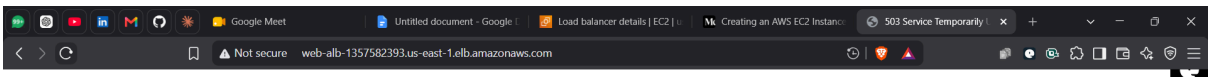

Wwlcome to server 2!

Wwlcome to server 1!

Problems faced

1) SSH connection isn't connected to the server with the security group only with my ip address
2) Can’t write or execute index.html file without changing the permissions
3) Webpage is not loading even after
   - “Sudo yum install https -y”
   - “Sudo systemctl start httpd”
   - “Sudo systemctl enable httpd”
4) Even if i allow https in the launch template i can’t open the file
5) Now I can open with the file but I need to change the https:// to http://, but why?

Target Group Health : healthy
Are both EC2 instances running: yes (tried both http only or https only or both in inbound and outbound rules)
Apache running : Active
ALB Listener : http → target group

503 Service Temporarily Unavailable
