Troubleshoot ELB Issues (15 Marks)
An Application Load Balancer is unable to serve the application.
Identify and resolve all configuration issues preventing successful access.

Problems faced

1) SSH connection isn't connected to the server with the security group only with my ip address
2) Can’t write or execute index.html file without changing the permissions
3) Webpage is not loading even after
   “Sudo yum install https -y”
   “Sudo systemctl start httpd”
   “Sudo systemctl enable httpd”
4) Even if i allow https in the launch template i can’t open the file
5) Now I can open with the file but I need to change the https:// to http://, but why?

Target Group Health : healthy
Are both EC2 instances running: yes (tried both http only or https only or both in inbound and outbound rules)
Apache running : Active
ALB Listener : http → target group

Troubleshoots measures

1) Security group to allow all traffic in inbound and outbound network traffic(which is not safe for production- probably use required protocols)
2) Check availability zones are same in both load balancer and instances
